> Extracting data &
random sampling demo

Extracting data

- We need to sort and extract specific data out of the managers data frame
- Load the managers data frame from Blackboard first and check for NA's during the loading process
- Convert the managers date field to a date variable
- Select records from the managers data frame between 15-10-18 and 01-11-18
- Drop the Q3 and Q4 attributes (variables) from the data frame
- Find records where the managers age between 23 – 35. For these records just show Q1 to Q4
- Select a subset of managers where gender = M and age > 25. Only show records from Gender to Q4 inclusive

Random sampling & sorting

- Select a random sample of 3 records from managers_data
- Extract 10 random samples from managers_data
- Sort the managers data frame by Age
- Sort Managers data frame by Gender and then by age within each gender
- Save the 10 random samples into a csv file called **random sample.csv**
